## **DFD for RETAIL - APPLICATION**

A Data Flow Diagram (DFD) for a developer typically represents the flow of data within a system, illustrating how data moves between different processes, data stores, and external entities. Below is a simple example of a DFD for a basic application, such as a user login system.

# **Level 0: Context Diagram**

- Users interact with the Retail App.
- The **Retail App** communicates with **MongoDB** to store and retrieve user details and product information.

# **Explanation:**

- External Entity (User): The User interacts with the Retail App.
- **Process (Retail App):** The system processes authentication, product browsing, cart management, and checkout.
- **Data Store (MongoDB):** The database stores user credentials, product details, cart items, and transaction history.

## Level 1 DFD (High-Level DFD)

• Breaking down the **Retail App** process into more detailed steps.

#### 1. User Authentication

- 1. User clicks **Sign Up** or **Login**.
- 2. If the user exists in **MongoDB**, they are logged in.
- 3. If not, they sign up, and details are stored in **MongoDB**.
- 4. After successful authentication, the **Product Catalogue Page** opens.

### 2. Product Catalogue

- 5. Displays product details fetched from **MongoDB**.
- 6. User can click "Add to Cart" to add products to the cart.

### 3. Cart Management

- 7. User can view the cart by clicking "View Cart".
- 8. Products added to the cart are stored in **MongoDB**.

#### 4. Payment

- 9. User can proceed to payment from the **Cart Page**.
- 10. Payment details are stored and processed.

### 5. Logout

11. Clicking **Logout** redirects the user to the **Login/Sign Up Page**.

### **Decomposition of Process - Retail App:**

In Level 1 of the Data Flow Diagram (DFD), we break down the Retail App process into multiple sub-processes that handle user authentication, product catalogue management, cart operations, payment processing, and logout functionality. Each process in the **Retail App DFD** represents a critical function, ensuring smooth e-commerce operations while maintaining **data integrity** and **efficient system interactions** with MongoDB and external services.

Breaking down the **Retail App** process into more detailed steps.

External Entities	++		
<b>♣</b> User	= Payment API		
++	+		
v  • Authentication & Payment	V		
++	++		
<i>/</i> 1.1 - User Login	💰 1.4 - Payment		
& Signup	Processing		
++	++		
	I		
v	v		
Data Storage			
++	++		
🌓 MongoDB (Users)	Payment		
++	++		
V			
Shopping Flow			
++			

+----+ | ■ 1.3 - Manage Cart | +----+  $\mathbf{v}$ Logout Flow +----+ | 1.5 - Logout | +----+ v +----+ Redirect to Login

# **Explanation:**

- 1. **Process 1.1 (User Authentication):** The user logs in or signs up. If credentials exist in **MongoDB**, they log in; otherwise, new user details are stored.
- 2. **Process 1.2 (View Products):** The user browses available products.
- 3. **Process 1.3 (Manage Cart):** The user adds/removes products from the cart, updating **Cart DB**.
- 4. **Process 1.4 (Payment Processing):** When proceeding to checkout, payment details are sent to an external **Payment API**.
- 5. **Process 1.5 (Logout):** The user logs out, and the system redirects them to the login page.
